

## Task 5.2C

The header uses flexbox with a collapsible hamburger menu (a hidden checkbox toggled by a label, no JavaScript) below 48rem, so that the navigation stays reachable with one thumb instead of eating screen space from 48rem it expands into an inline row across the header.

CSS grid organizes the feature cards, result cards, and footer links into a single column on mobile and three columns from 48rem. So, related content groups visually rather than running as one long scroll. A 2nd breakpoint at 64rem widens the hero image/copy split and increases section padding and grid gaps, giving the page breathing room on larger monitors instead of just stretching mobile spacing.

Headings use `clamp()` with `vw` units so font size scales smoothly across the whole range instead of jumping at each breakpoint.

### The Responsive Table

The new "Compare across scanned products" table lists four yoghurt products against their key additive, category, and a shopper note.

On smaller screens, the table can be scrolled sideways instead of squeezing all the columns together. The table keeps a minimum width so the content stays readable and does not wrap awkwardly. The intro text and the caption also make it clear that users can scroll or swipe across the table to view the remaining columns.

### All Changes

Changes:

- In 5.1P, the navigation was always expanded. In this version, I added a collapsible hamburger menu so the navigation works better on smaller screens.
- 5.1P only used one breakpoint. I added another breakpoint at 64rem to make some extra layout adjustments for wider desktop screens.
- I added a responsive comparison table that can scroll horizontally on smaller screens, so the columns stay readable instead of getting squeezed together.
- I changed the heading sizes to use `clamp()` and `vw`, allowing them to scale more smoothly depending on the screen size.
- I also added more comments throughout the CSS to explain what each section does and why the different responsive techniques are being used.

Updated navigation bar:

#### FOOD LABEL DECODER

## Read the label. Understand every additive.

LabelLens helps shoppers in Australia check ingredient lists, E numbers, and processing aids before they put a product in the trolley.

[Scan a label](#)
[Search an additive](#)

#### LOOKUP

##### Search by name or E-number

Type a code such as E211, or a common name such as sodium benzoate. LabelLens matches it to a short safety note and typical uses in packaged food.

##### Additive name or E-number

[Search](#)

Or try one of these:

#### How LabelLens helps

##### Scan the pack

Photograph the ingredients list. LabelLens highlights names and codes so you can confirm what was detected before you save the scan.

##### Plain-language notes

Each additive is explained in everyday language, including why it is added and whether it is commonly flagged for people with sensitivities.

##### Compare products

Place two or three similar foods side by side to see which recipe uses fewer colours, preservatives, or flavour enhancers.

#### CAMERA WORKFLOW

## Scan and confirm the ingredients

Hold the pack steady so the ingredients panel fills the frame. After the photo is taken, check each detected additive before you open the results.
