

Task 8.3D

Self Reflection

This was pretty straightforward. Everything here, I have done before.

I picked the character counter, real-time validation, and conditional show/hide because they're the three that actually matters for a contact form. Users can see the message limit while typing, and gets told straight away if the email or phone is wrong instead of only after pressing submit.

The scan date and additive fields only shows when their reason is about a scan. There's no point cluttering the form with fields they don't need otherwise.

For regex, I used the full RFC 5322 email pattern straight from regular-expressions.info instead of using some simplified on that I wrote myself or something from [stackoverflow](https://stackoverflow.com). For phone numbers, I used E164 based on the RFC 3966 tel URI spec. So both are following an actual standard, and not just a guess. However, for phone numbers, using a library like google's [libphonenumber](https://github.com/google/libphonenumber) is the industry standard and works much better, even with multiple formatting approaches.

The only real issue was the RFC 5322 pattern having a raw / inside the character class. This breaks a JavaScript regex literal unless it's escaped. Was a quick fix once I spotted it.

For the layout, I kept the same responsive grid from 6.3D. It already suits Raj scanning quickly inside a store and Madison filling it in later at home. The inline feedback and character counter just makes the errors more obvious, without needing to zoom or guess.
